

# System Workflow Specification

## AI INTEGRATION & ARCHITECTURE DOCUMENTATION

---

This document provides a formal specification of the automated system workflows utilizing Artificial Intelligence (AI) services to streamline customer request handling, optimize inputs, and classify service requests accurately.

### **1. Service Category Classification Workflow**

This workflow governs how customer problem statements are dynamically analyzed and categorized using an AI model, with manual override safeguards to ensure data integrity before submission.

| STEP   | PROCESS COMPONENT  | FUNCTIONAL DESCRIPTION                                                                                      |
|--------|--------------------|-------------------------------------------------------------------------------------------------------------|
| Step 1 | Input Capture      | The customer inputs a free-form textual description detailing their technical problem or request.           |
| Step 2 | Payload Forwarding | The system serializes the user input text and safely dispatches it via API to the AI classification engine. |
| Step 3 | AI Evaluation      |                                                                                                             |

| STEP   | PROCESS COMPONENT       | FUNCTIONAL DESCRIPTION                                                                                                                                  |
|--------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
|        |                         | The AI model processes the semantic context of the text and assigns the best-fitting pre-defined category.                                              |
| Step 4 | Suggestion Presentation | The interface updates to display the recommended category to the customer for transparency.                                                             |
| Step 5 | Validation Gateway      | The customer evaluates the accuracy. Acceptance routes directly to confirmation, while rejection opens a dropdown selection menu for manual overriding. |
| Step 6 | Final Submission        | The application records the final verified category and submits the complete request ticket to the database.                                            |

## 2. Description Improvement Optimization Workflow

This workflow outlines the text optimization subsystem designed to parse brief, incomplete, or ambiguous customer descriptions and automatically rewrite them for maximum clarity.

| STEP   | PROCESS COMPONENT      | FUNCTIONAL DESCRIPTION                                                                                                           |
|--------|------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Initial Input          | The user provides basic, informal, or shorthand text regarding their issue.                                                      |
| Step 2 | AI Submission          | The application framework encapsulates the text and prompts the LLM/AI model for rewriting and clarification.                    |
| Step 3 | Generative Enhancement | The AI clarifies grammar, expands shorthand terminology, structures bullet points, and builds a comprehensive description block. |
| Step 4 | Review Interface       | The generated clean text is displayed in a side-by-side or layered preview panel for user verification.                          |
| Step 5 | Interactive Editing    | The customer reviews and has full access to manually edit any auto-generated phrases to match their precise needs.               |
| Step 6 | Finalization           | The final refined text block is approved, locked, and transmitted to fulfill the backend operation queue.                        |
